 - Angular momentum
 - SU(d) generators
 - Detection of singlets

Why spin squeezing inequalities for $j > \frac{1}{2}$ is important?

- Many experiments are aiming to create entangled states with many atoms.
- Only collective quantities can be measured.
- Most experiments use atoms with $j > \frac{1}{2}$.

Genuine multipartite entanglement

Definition

A state is (fully) separable if it can be written as

$$\sum_{k} p_{k} \varrho_{1}^{(k)} \otimes \varrho_{2}^{(k)} \otimes ... \otimes \varrho_{N}^{(k)}.$$

Definition

A pure multi-qubit quantum state is called biseparable if it can be written as the tensor product of two multi-qubit states

$$|\Psi\rangle = |\Psi_1\rangle \otimes |\Psi_2\rangle.$$

Here $|\Psi\rangle$ is an *N*-qubit state. A mixed state is called biseparable, if it can be obtained by mixing pure biseparable states.

Definition

If a state is not biseparable then it is called genuine multi-partite entangled.

k-producibility/k-entanglement

Definition

A pure state is *k*-producible if it can be written as

$$|\Phi\rangle = |\Phi_1\rangle \otimes |\Phi_2\rangle \otimes |\Phi_3\rangle \otimes |\Phi_4\rangle$$

where $|\Phi_I\rangle$ are states of at most k qubits. A mixed state is k-producible, if it is a mixture of k-producible pure states.

[O. Gühne and G. Tóth, New J. Phys 2005.]

- In many-particle systems where only collective quantities can be detected, this is the only meaningful characterization of entanglement.
- That is, genuine multipartite entanglement is very difficult to detect in such systems.

- Motivation
 - Why spin squeezing inequalities are important?
- Multipartite entanglement

Physical systems

State-of-the-art in experiments

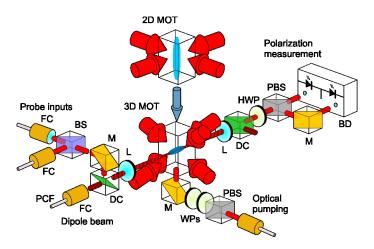

- 100,000 atoms realizing an array of 1D Ising spin chains (Nature, 2003)
- Spin squeezing with 10⁶ 10¹² atoms (Nature, 2001)

Main challenge

- The particles cannot be addressed individually.
- Only collective quantities can be measured.
- New type of entangled states and entanglement criteria are needed.

Physical systems II

For example: Spin squeezing in a cold atomic ensemble (not BEC!)

Picture from M.W. Mitchell, ICFO, Barcelona.

 - Detection of singlets

Many-particle systems for j=1/2

 For spin-¹/₂ particles, we can measure the collective angular momentum operators:

$$J_I := \frac{1}{2} \sum_{k=1}^N \sigma_I^{(k)},$$

where I = x, y, z and $\sigma_I^{(k)}$ a Pauli spin matrices.

We can also measure the

$$(\Delta J_I)^2 := \langle J_I^2 \rangle - \langle J_I \rangle^2$$

variances.

- Motivation

 - Angular momentum
 - SU(d) generators
 - Detection of singlets

Squeezing

The variances of the two quadrature components are bounded

$$(\Delta x)^2 (\Delta p)^2 \ge const.$$

- Coherent states saturate the inequality.
- Squeezed states are the states for which one of the quadrature components have a smaller variance than for a coherent state.
- Can one use similar ideas for spin systems?

- Motivation
 - Why spin squeezing inequalities are important?
- Multipartite entanglement

- Spin squeezing inequality for an ensemble of spin-j atoms
 - Basic idea for $j > \frac{1}{2}$
 - Angular momentum
 - SU(d) generators
 - Detection of singlets

Spin squeezing

 The variances of the angular momentum components are bounded

$$(\Delta J_x)^2 (\Delta J_y)^2 \geq \frac{1}{4} |\langle J_z \rangle|^2.$$

If $(\Delta J_x)^2$ is smaller than the standard quantum limit $\frac{|\langle Jz\rangle|}{2}$ then the state is called spin squeezed.

- z is the direction of the mean spin!
- The angular momentum of such a state has a small variance in one direction.
- The variance is large in an orthogonal direction.

[M. Kitagawa and M. Ueda, PRA {\bf 47}, 5138 (1993).]

- Motivation
 - Why spin squeezing inequalities are important?
- Multipartite entanglement
 - Quantum experiments with cold gases
 - Physical systems
 - Collective measurements
- Spin squeezing
 - Squeezing
 - Spin squeezing
- **5** Spin squeezing criteria for j = 1/2

The standard spin-squeezing criterion

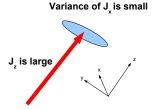

The spin squeezing criteria for entanglement detection is

$$\frac{(\Delta J_x)^2}{\langle J_y \rangle^2 + \langle J_z \rangle^2} \ge \frac{1}{N}.$$

If it is violated then the state is entangled.

[A. Sørensen, L.M. Duan, J.I. Cirac, P. Zoller, Nature 409, 63 (2001).]

States violating it are like this:

- Motivation
 - Why spin squeezing inequalities are important?
- Multipartite entanglement
 - Quantum experiments with cold gases
 - Physical systems
 - Collective measurements
- Spin squeezing
 - Squeezing
 - Spin squeezing
- **5** Spin squeezing criteria for j = 1/2
 - The original criterion
 - Generalized criteria for $j = \frac{1}{2}$

 - Basic idea for $j > \frac{1}{2}$
 - Angular momentum
 - SU(d) generators
 - Detection of singlets

Generalized spin squeezing criteria for $j=\frac{1}{2}$

Let us assume that for a system we know only

$$\vec{J} := (\langle J_X \rangle, \langle J_Y \rangle, \langle J_Z \rangle),$$

 $\vec{K} := (\langle J_X^2 \rangle, \langle J_Y^2 \rangle, \langle J_Z^2 \rangle).$

Then any state violating the following inequalities is entangled

$$\langle J_x^2 \rangle + \langle J_y^2 \rangle + \langle J_z^2 \rangle \leq \frac{N(N+2)}{4},$$

$$(\Delta J_x)^2 + (\Delta J_y)^2 + (\Delta J_z)^2 \geq \frac{N}{2},$$

$$\langle J_k^2 \rangle + \langle J_I^2 \rangle \leq (N-1)(\Delta J_m)^2 + \frac{N}{2},$$

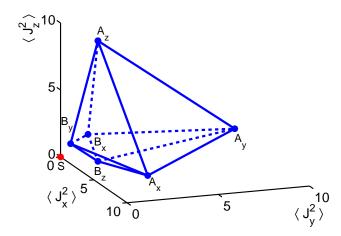

$$(N-1) \left[(\Delta J_k)^2 + (\Delta J_I)^2 \right] \geq \langle J_m^2 \rangle + \frac{N(N-2)}{4},$$

where k, l, m take all the possible permutations of x, y, z.

[GT, C. Knapp, O. G\"uhne, and H.J. Briegel, PRL 99, 250405 (2007); quant-ph/0702219.]

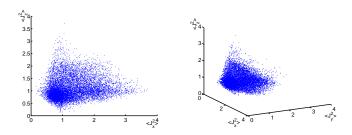

Generalized spin squeezing criteria for $j = \frac{1}{2}$

- The previous inequalities, for fixed $\langle J_{x/y/z} \rangle$, describe a polytope in the $\langle J_{x/y/z}^2 \rangle$ space. The polytope has six extreme points: $A_{x/y/z}$ and $B_{x/y/z}$.
- For $\langle \vec{J} \rangle = 0$ and N = 6 the polytope is the following:

Completeness

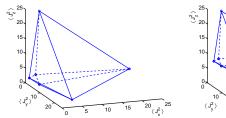

Random separable states:

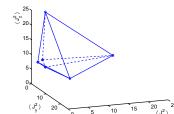

• The completeness can be proved for large *N*.

• The polytope for N = 10 and J = (0,0,0),

$$J = (0, 0, 2.5),$$

and
$$J = (0, 0, 4.5)$$
.

Bound entangled states

- The inequalities detect bound entangled states in the thermal states of Heisenberg spin models.
- These states have a positive partial transpose (PPT) with respect to all bipartitions.

- Motivation
 - Why spin squeezing inequalities are important?
- Multipartite entanglement

 - The original criterion
 - Generalized criteria for $j = \frac{1}{2}$
- 6 Spin squeezing inequality for an ensemble of spin-j atoms
 - Basic idea for $j > \frac{1}{2}$
 - Angular momentum
 - SU(d) generators
 - Detection of singlets

Basic ideas for the $j > \frac{1}{2}$ case

- Particles with d>2 internal states.
- a_k for k=1,2,...,M denote single-particle operators with the property $\text{Tr}(a_k a_l) = C\delta_{kl}$, where C is a constant.
- We need the upper bound K for the inequality $\sum_{k=1}^{M} \langle a_k^{(n)} \rangle^2 \leq K$.
- The N-qudit collective operators used in our criteria will be denoted by

$$A_k = \sum_n a_k^{(n)}.$$

"Modified" quantities for $j > \frac{1}{2}$

- For the $j = \frac{1}{2}$ case, the SSIs were developed based on the first and second moments and variances of the such collective operators.
- For the $j > \frac{1}{2}$ case, we define the modified second moment

$$\langle \tilde{A}_k^2 \rangle := \langle A_k^2 \rangle - \langle \sum_n (a_k^{(n)})^2 \rangle = \sum_{m \neq n} \langle a_k^{(n)} a_k^{(m)} \rangle$$

and the modified variance

$$(\tilde{\Delta}A_k)^2 := (\Delta A_k)^2 - \langle \sum_n (a_k^{(n)})^2 \rangle.$$

• These are essential to get tight equations for $j > \frac{1}{2}$.

Basic equation

 For separable states, i.e., for states that can be written as a mixture of product states,

$$(N-1)\sum_{k\in I}(\tilde{\Delta}A_k)^2-\sum_{k\notin I}\langle (\tilde{A}_k)^2\rangle\geq -N(N-1)K$$

holds, where each index set $I \subseteq \{1, 2, ..., M\}$ defines one of the 2^M inequalities.

• Note that $I = \emptyset$ and $I = \{1, 2, ..., M\}$ are among the possibilities.

Derivation

- We consider product states of the form $|\Phi\rangle = \otimes_n |\phi_n\rangle$. For such states, we have $(\Delta \tilde{A}_k)^2_{\Phi} = -\sum_n \langle a_k^{(n)} \rangle^2$.
- Hence, the left-hand side of the inequality equals

$$-\sum_{n}(N-1)\sum_{k\in I}\langle a_{k}^{(n)}\rangle^{2} - \sum_{k\notin I}\left(\langle A_{k}\rangle^{2} - \sum_{n}\langle a_{k}^{(n)}\rangle^{2}\right)$$
$$\geq -\sum_{n}(N-1)\sum_{k=1}^{M}\langle a_{k}^{(n)}\rangle^{2} \geq -N(N-1)K$$

- We used that $\langle A_k \rangle^2 \leq N \sum_n \langle a_k^{(n)} \rangle^2$.
- The equation is saturated by all states of the form $|\phi\rangle^{\otimes N}$.

The inequalities for $j > \frac{1}{2}$ with the angular momentum coordinates

Application 1:

$$a_k = \{j_x, j_y, j_z\}.$$

• For spin-j particles for $j > \frac{1}{2}$, we can measure the collective angular momentum operators:

$$J_l := \sum_{k=1}^N j_l^{(k)},$$

where I = x, y, z and $j_I^{(k)}$ are the angular momentum coordinates [i.e., SU(2) generators].

We can also measure the

$$(\Delta J_l)^2 := \langle J_l^2 \rangle - \langle J_l \rangle^2$$

variances.

The inequalities for $j > \frac{1}{2}$ with the angular momentum coordinates II

 For fully separable states of spin-j particles, all the following inequalities are fulfilled

$$\begin{split} \langle J_x^2 \rangle + \langle J_y^2 \rangle + \langle J_z^2 \rangle & \leq & Nj(Nj+1), \\ (\Delta J_x)^2 + (\Delta J_y)^2 + (\Delta J_z)^2 & \geq & Nj, \\ \langle \tilde{J}_k^2 \rangle + \langle \tilde{J}_l^2 \rangle - N(N-1)j^2 & \leq & (N-1)(\tilde{\Delta}J_m)^2, \\ (N-1)\left[(\tilde{\Delta}J_k)^2 + (\tilde{\Delta}J_l)^2\right] & \geq & \langle \tilde{J}_m^2 \rangle - N(N-1)j^2, \end{split}$$

where k, l, m take all possible permutations of x, y, z.

Violation of any of the inequalities implies entanglement.

Completeness

- In the large N limit, the inequalities with the angular momentum are complete.
- That is, it is not possible to come up with a new entanglement conditions with based on $\langle J_k \rangle$ and seed on $\langle J_k \rangle$ and $\langle \tilde{J}_k^2 \rangle$ that detect states not detected by these inequalities.

Mapping qubit inequalities to qudits

Take an inequality valid for N-qubit separable states of the form

$$f(\{\langle J_l \rangle\}_{l=x,y,z}, \{\langle \tilde{J}_l^2 \rangle\}_{l=x,y,z}) \ge \text{const.},$$

where f is a concave function. All of the generalized SSIs have this form.

 An entanglement condition can be transformed to a criterion for a system of N spin-j particles by the substitution

$$\langle J_l \rangle \quad \rightarrow \quad \frac{1}{2j} \langle J_l \rangle, \qquad \langle \tilde{J}_l^2 \rangle \rightarrow \frac{1}{4j^2} (\langle \tilde{J}_l^2 \rangle).$$

The standard spin-squeezing inequality becomes

$$\frac{(\Delta J_x)^2}{\langle J_y \rangle^2 + \langle J_z \rangle^2} + \frac{\sum_n (j^2 - \langle (j_x^{(n)})^2 \rangle)}{\langle J_y \rangle^2 + \langle J_z \rangle^2} \geq \frac{1}{N}.$$

This inequality is violated only if there is entanglement between the spin-*j* particles.

- Due to the second, nonnegative term on the left-hand side, for $j > \frac{1}{2}$ there are states that violate the original inequality, but do not violate this one. Thus, there is spin squeezing without entanglement between the particles.
- Our spin squeezing inequalities are strictly stronger than the original inequality.

- Motivation
 - Why spin squeezing inequalities are important?
- Multipartite entanglement
 - Quantum experiments with cold gases
 - Physical systems
 - Collective measurements
- Spin squeezing
 - Squeezing
 - Spin squeezing
- **5** Spin squeezing criteria for j = 1/2
 - The original criterion
 - Generalized criteria for $j = \frac{1}{2}$
- 6 Spin squeezing inequality for an ensemble of spin-j atoms
 - Basic idea for $j > \frac{1}{2}$
 - Angular momentum
 - SU(d) generators
 - Detection of singlets

The inequalities for $j > \frac{1}{2}$ with the G_k 's

Application 2:

$$a_k = SU(d)$$
 generators.

• For spin-j particles for j > 1/2, we can measure the collective operators:

$$G_I:=\sum_{k=1}^N g_I^{(k)},$$

where $I = 1, 2, ..., d^2 - 1$ and $g_I^{(k)}$ are the SU(d) generators.

We can also measure the

$$(\Delta G_I)^2 := \langle G_I^2 \rangle - \langle G_I \rangle^2$$

variances.

The inequalities for $j > \frac{1}{2}$ with the G_k 's

- For a system of d-dimensional particles, we can define collective operators based on the SU(d) generators $\{g_k\}_{k=1}^M$ with $M = d^2 1$ as $G_k = \sum_{n=1}^N g_k^{(n)}$.
- The SSIs for G_k have the general form

$$(N-1)\sum_{k\in I}(\tilde{\Delta}G_k)^2-\sum_{k\notin I}\langle(\tilde{G}_k)^2\rangle\geq -2N(N-1)\frac{(d-1)}{d}.$$

For instance, for the d=3 case, the SU(d) generators can be the eight Gell-Mann matrices.

• I is a subset of indices between 1 and M. We have 2^M equations!

- Motivation
 - Why spin squeezing inequalities are important?

One of the generalized spin squeezing criteria

A condition for separability is

$$\sum_k (\Delta G_k)^2 \geq 2N(d-1).$$

[G. Vitagliano, P. Hyllus, I.L. Egusquiza, and G. Tóth, Optimal spin squeezing inequalities for arbitrary spin, arXiv:1104.3147.]

Maximally violating states

- For N = d, the multipartite singlet state maximally violates the condition with $\sum_k (\Delta G_k)^2 = 0$.
- For N < d, there is no quantum states for which $\sum_{k} (\Delta G_k)^2 = 0$.
- This can be seen as follows. It is not possible to create a completely
 antisymmetric state of *d*-state particles with less than *d* particles.

The criterion

A condition for two-producibility for N qudits of dimension d is

$$\sum_{k} (\Delta G_k)^2 \ge 2N(d-2).$$

A condition for separability is

$$\sum_{k} (\Delta G_k)^2 \ge 2N(d-1).$$

Noise tolerance

• Let us consider SU(d) singlet states (i.e., states with $\langle G_k^2 \rangle = 0$) mixed with white noise as

$$\varrho_{\text{noisy}} = (1 - p_{\text{noise}})\varrho_{\text{singlet}} + p_{\text{noise}} \frac{1}{d^N} \mathbb{1}.$$

 Direct calculation shows that such a state is detected as entangled if

$$p_{\text{noise}} < \frac{d}{d+1}$$
.

Thus, the noise tolerance in detecting SU(d) singlets is increasing with d!

Advantages of criteria for $j > \frac{1}{2}$

- Most atoms have $j > \frac{1}{2}$. No need to create spin-1/2 subsystems artificially
- Manipulation is possible with magnetic fields rather than with lasers.
- New experiments can be proposed.

Topics

- Multipartite entanglement and its detection
- Metrology, cold gases
- Collaborating on experiments:
 - Weinfurter group, Munich, (photons)
 - Mitchell group, Barcelona, (cold gases)

Funding:

- European Research Council starting grant 2011-2016,
 1.3 million euros
- CHIST-ERA QUASAR collaborative EU project
- Grants of the Spanish Government and the Basque Government

Summary

- We presented a full set of generalized spin squeezing inequalities with the angular momentum coordinates for j>1/2.
- We presented a large set of inequalities with the other collective operators that can be measured.
- These might make possible new experiments and make existing experiments simpler.
