## Entanglement measures (How much is it entangled?) Motivation

- A. General quantum operation
- B. Local operations and classical communication (LOCC)
- C. Entanglement of formation
- D. Concurrence
- E. Entanglement of distillation
- F. Bound entanglement
- G. Negativity

• After detecting entanglement, we have to ask how entangled the state is.

• It will turn out that entanglement is a resource.

## Entanglement measures (How much is it entangled?)

Motivation

#### • A. General quantum operation

- B. Local operations and classical communication (LOCC)
- C. Entanglement of formation
- D. Concurrence
- E. Entanglement of distillation
- F. Bound entanglement
- G. Negativity

#### General quantum operation

• The general quantum operation is defined as

$$\varrho' = \sum_{k} \mathsf{E}_{k} \varrho \mathsf{E}_{k}^{\dagger}$$

with

$$\sum_{k} E_{k}^{\dagger} E_{k} = 1.$$

- $E_k$  are Kraus operators.
- Generalized measurements, POVM (positive operator-valued measure).
- Special case: von Neumann measurements, when *E<sub>k</sub>* are pairwise orthogonal projectors.
- Naimark's dilation theorem: general operation= von Neumann measurement on system+ancilla.

#### Entanglement measures (How much is it entangled?)

- Motivation
- A. General quantum operation
- B. Local operations and classical communication (LOCC)
- C. Entanglement of formation
- D. Concurrence
- E. Entanglement of distillation
- F. Bound entanglement
- G. Negativity

## Local operations and classical communication (LOCC)

#### LOCC are

- local unitaries,
- local von Neumann or POVM measurements,
- local unitaries or measurements conditioned on measurement outcomes on the other party.
- Mathematical description of LOCC. Separable operations are a somewhat larger set, however, this set can easily be described.

$$arrho' = \sum_{k} E_{k}^{(1)} \otimes E_{k}^{(2)} \varrho \left( E_{k}^{(1)} \otimes E_{k}^{(2)} 
ight)^{\dagger}$$

with

$$\sum_{k} \left( \boldsymbol{E}_{k}^{(1)} \otimes \boldsymbol{E}_{k}^{(2)} \right)^{\dagger} \left( \boldsymbol{E}_{k}^{(1)} \otimes \boldsymbol{E}_{k}^{(2)} \right) = 1.$$

# Local operations and classical communication (LOCC) II

 Stochastic Local Operations and Classical Communication (SLOCC):

$$|\Psi\rangle' \leftarrow E_k^{(1)} \otimes E_k^{(2)} |\Psi\rangle$$

It happens with some probability, not deterministic.

- LOCC cannot create entanglement. Separable states remain separable under LOCC.
- LOCC can create correlations.

#### Entanglement measures (How much is it entangled?)

- Motivation
- A. General quantum operation
- B. Local operations and classical communication (LOCC)

#### • C. Entanglement of formation

- D. Concurrence
- E. Entanglement of distillation
- F. Bound entanglement
- G. Negativity

#### **Entropy of entanglement**

• The von Neumann entropy is defined as

$$S(\varrho) = -\mathrm{Tr}(\varrho \log_2 \varrho).$$

It can be written with the eigenvalues of the density matrix as

$$S(\varrho) = -\sum_{k=1}^{d} \lambda_k \log_2 \lambda_k.$$

- For a pure state we have  $\lambda_k = \{1, 0, 0, ..., 0\}$ , and thus it is zero.
- Its maximal is for the completely mixed state for which  $\lambda_k = \{\frac{1}{d}, \frac{1}{d}, \frac{1}{d}, ..., \frac{1}{d}\}$ , and its value is  $\log_2 d$ .
- For a bipartite pure state, the entropy of entanglement is

$$E_E(|\Psi\rangle) = S(Tr_1(|\Psi\rangle\langle\Psi|)).$$

That is, it is the von Neumann entropy of the reduced state is an entaglement measure.

#### Comments

- It is one for two-qubit singlet states.
- It is zero for product states.
- It is invariant under  $U_1 \otimes U_2$ .

#### **Entanglement of formation**

 For mixed states, the entanglement of formation is the convex roof of the von Neumann entropy of the reduced state.

$$E_F = \min_{|\Psi_k\rangle, p_k} \sum_k p_k E_E(|\Psi_k\rangle),$$

The optimization is over all decompositions of the state of the type

$$\varrho = \sum_{k} p_{k} |\Psi_{k}\rangle \langle \Psi_{k}|.$$

- *E<sub>F</sub>* tells us, in the asymptotic limit, how many singlets we need to create the state.
- Is it easy to compute? No. For 2 × 2 systems, there is an explicit formula with the concurrence. For larger systems, there is not a general method.

#### Entanglement measures (How much is it entangled?)

- Motivation
- A. General quantum operation
- B. Local operations and classical communication (LOCC)
- C. Entanglement of formation

#### D. Concurrence

- E. Entanglement of distillation
- F. Bound entanglement
- G. Negativity

#### **Entanglement of formation**

- For two qubits,  $E_F$  can be calculated explicitly (Wootters, 1997).
- The concurrence is defined as

$$\mathcal{C}(arrho)=\mathsf{max}(\mathsf{0},\lambda_1-\lambda_2-\lambda_3-\lambda_4),$$

where  $\lambda_k$ 's are, in a decreasing order, the eigenvalues of

$$R=\sqrt{\sqrt{arrho}arrho}\sqrt{arrho}arrho},$$

and

$$\tilde{\varrho} = (\sigma_y \otimes \sigma_y) \varrho^* (\sigma_y \otimes \sigma_y).$$

We also nee that

$$\epsilon(c) = H_2\left(rac{1+\sqrt{1-c^2}}{2}
ight).$$

Here

$$H_2 = -x \log_2 x - (1-x) \log_2(1-x).$$

• Then, E<sub>F</sub> can be obtained as

$$E_F(\varrho) = \epsilon(C(\varrho)).$$

Special case: for pure states

$$C(|\Psi\rangle) = |\langle \Psi | \tilde{\Psi} \rangle| = 2|a_{11}a_{22} - a_{12}a_{21}|,$$

where

$$|\Psi
angle = egin{pmatrix} a_{11}\ a_{12}\ a_{21}\ a_{22} \end{pmatrix}.$$

#### Entanglement measures (How much is it entangled?)

- Motivation
- A. General quantum operation
- B. Local operations and classical communication (LOCC)
- C. Entanglement of formation
- D. Concurrence

#### • E. Entanglement of distillation

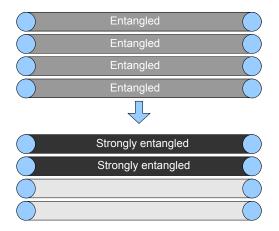

- F. Bound entanglement
- G. Negativity

• *E<sub>D</sub>* tells us, how many singlets we can obtain from the state with LOCC. In general,

$$E_F \geq E_D$$
.

• Note that local operation and classical communication means that we have several copies and we can act on the copies locally.

#### **Entanglement of distillation II**

#### Entanglement measures (How much is it entangled?)

- Motivation
- A. General quantum operation
- B. Local operations and classical communication (LOCC)
- C. Entanglement of formation
- D. Concurrence
- E. Entanglement of distillation
- F. Bound entanglement
- G. Negativity

- There are states that need entangled particles to be created, but singlets cannot be distilled from them.
- All PPT entangled states are like that. (That is, all entangled states that are not detected by the Peres-Horodecki criterion.)

#### **Bound entanglement II**

 Next, we will prove this. First we show that PPT state remain PPT under LOCC. Under LOCC we have

$$arrho' = \sum_{k} E_{k}^{(1)} \otimes E_{k}^{(2)} \varrho \left( E_{k}^{(1)} \otimes E_{k}^{(2)} 
ight)^{\dagger}$$

We also have

$$(\varrho')^{T2} = \sum_{k} E_{k}^{(1)} \otimes ((E_{k}^{(2)})^{\dagger})^{T} \varrho^{T2} (E_{k}^{(1)})^{\dagger} \otimes (E_{k}^{(2)})^{T}$$

Here we used that  $(AB)^T = B^T A^T$  and  $A^{\dagger} = (A^*)^T$ .

We can see that if *Q*<sup>T2</sup> ≥ 0 then (*Q'*)<sup>T2</sup> ≥ 0. Thus the PPT states remain PPT under LOCC.

R., P., M., and K. Horodecki, Rev. Mod. Phys. 81, 865 (2009). (Click on the link above, see "G. Bound entanglement - when distillability fails" on page 44.)

• Let us again remember the flip operator

$$F|k\rangle|l\rangle = |l\rangle|k\rangle$$

It has eigenvalues  $\pm 1$ .

• The maximally entangled state

$$|\Psi_{\rm me}\rangle = \frac{1}{\sqrt{d}}\sum_{k=1}^{d}|k\rangle|k\rangle.$$

We can show that

$$\begin{split} |\Psi_{\rm me}\rangle\langle\Psi_{\rm me}| &= \frac{1}{d}\sum_{k,l}^{d}|k\rangle\langle l|\otimes|k\rangle\langle l|,\\ |\Psi_{\rm me}\rangle\langle\Psi_{\rm me}|^{T1} &= \frac{1}{d}\sum_{k,l}^{d}|k\rangle\langle l|\otimes|l\rangle\langle k|\equiv\frac{F}{d}. \end{split}$$

 Now we show that PPT states have a small overlap with the maximally entangled state. For PPT states, the fidelity with respect to the maximally entangled state is

$$\operatorname{Tr}(|\Psi_{\mathrm{me}}\rangle\langle\Psi_{\mathrm{me}}|\varrho) = \operatorname{Tr}(|\Psi_{\mathrm{me}}\rangle\langle\Psi_{\mathrm{me}}|^{T_1}\varrho^{T_1}) = \frac{1}{d}\operatorname{Tr}(F\varrho^{T_1}) \leq \frac{1}{d},$$

since  $\rho^{T1} \ge 0$  and *F* has  $\pm 1$  eigenvalues.

- Thus, PPT states have a small fidelity with respect to the maximally entangled state. Even LOCC operations cannot increase this.
- A simple product state can reach 1/d

$$\operatorname{Tr}(|\Psi_{\mathrm{me}}\rangle\langle\Psi_{\mathrm{me}}||11\rangle\langle11|) = \frac{1}{d}.$$

#### Entanglement measures (How much is it entangled?)

- Motivation
- A. General quantum operation
- B. Local operations and classical communication (LOCC)
- C. Entanglement of formation
- D. Concurrence
- E. Entanglement of distillation
- F. Bound entanglement
- G. Negativity

## Negativity

• Example for a monotone: negativity

$$N(\varrho) = \frac{\|\varrho^{\mathrm{T1}}\| - 1}{2}.$$

Trace norm=sum of singular values.

• For Hermitian matrices, it is the same as sum of eigenvalues.

$$N(\varrho) = \frac{\sum_k |\lambda_k| - 1}{2}$$

• Note that  $\sum_k \lambda_k = 1$ . Then, assume that the first *M* eigenvalues are negative, the rest is positive. We get

$$N(\varrho) = \frac{\sum_{k=1}^{M} -\lambda_k + \sum_{k=M+1}^{d} \lambda_k - \sum_k \lambda_k}{2}.$$

#### Hence,

$$N(\varrho) = \sum_{k=1}^{M} |\lambda_k|.$$

That is, the absolute value of the sum of the negative eigenvalues of the partial transpose.

- Clearly, it is zero for PPT states.
- Not as meaningful as the Entanglement of Formation, but can be calculated on any system sizes.
- It fulfills certain conditions on how it changes under LOCC. It does not increase under deterministic LOCC.
